A Synopsis of the Brazilian Taxa of Phyllanthus Section Phyllanthus (Euphorbiaceae)

Grady L. Webster
Herbarium, Section of Plant Biology, University of California, Davis, California 95616

Abstract: The synopsis of Phyllanthus section Phyllanthus in Brazil treats 4 subsections (2 of them newly described) including 30 species. A new subsection Almadenses is described based on Phyllanthus almadensis Müll. Arg., a species from Bahia, Brazil with a unique growth pattern. Another new subsection Claussenianis is proposed; it includes 17 species, all endemic to Brazil. Seven new species in this subsection are described: Phyllanthus aleemii, P. atalaensis, P. caparaoaensis, P. carvalhoni, P. mokotensis, P. piraniai, and P. sincorensis. A key to the Brazilian sections of subgenus Phyllanthus is provided, as well as synoptic keys and descriptions for the two new subsections and subsections Niruri and Swartzian.

Keywords: Euphorbiaceae, Phyllanthus, subsection Almadenses, subsection Claussenianis, subsection Niruri, subsection Swartzian, Brazil.

Phyllanthus L., the third largest genus of Euphorbiaceae, with more than 800 species (Govaerts et al., 2000), is represented in the Neotropics by 8 subgenera, 33 sections, and approximately 200 species (Webster, ined.). A considerable number of new sections and species have been described since the synopsis of the West Indian taxa (Webster, 1956-58). In that study, it was shown that pollen morphology provides critical characters for determining phylogenetic affinity; those light microscopic observations have recently been confirmed and extended using scanning electron microscopy (Webster and Carpenter, 2002).

In the current circumscription of Phyllanthus subgenus Phyllanthus (Webster, 1970), most of the species belong to section Phyllanthus, in which the habit is herbaceous or shrubby, branching is phyllanthoid (Webster, 1957) and the androecium consists of 2 or 3 (rarely 4) stamens. Four of the five American subsections of section Phyllanthus occur in Brazil, which has a total of approximately 30 species. Since the treatment of Müller in the Flora Brasiliensis (1873), there has not been an overall review of the Brazilian species of section Phyllanthus, although a few species have been treated by Webster (1959), Jablonski (1967), Smith et al. (1988), and Cordeiro (1989, 1992). The overall similarity in habit and the very small flowers of many species cause difficulties in identification; a high percentage of the specimens in herbaria are mis-determined. There appear to be polyploid complexes in subsections Claussenianis, Niruri, and Swartzian (Mangenot et al., 1977), and a considerable number of fragmentary specimens cannot be determined with certainty. The relationships of the two autocathederal subsections, Almadenses and Claussenianis, await clarification.

It is now clear that subsection Claussenianis, with 17 species—7 of which are here described as new—is the most speciose group of herbaceous and suffruticos species of Phyllanthus in Brazil. It is notable that the distribution of the subsection is entirely extra-Amazonian; in the Amazon basin, it is replaced by species of subsection Swartzianis. Discussions of the characteristic non-Amazonian habitats in eastern Brazil may be found in Eiten and Goodland (1979) and in Rizzini (1979).

Species of section Phyllanthus have long been of considerable ethnobotanical interest, particularly for their use in folk medicine to treat liver or bladder ailments (Uphof, 1968). For Brazil, Corréa (1969)
listed medicinal species that belong to three subsections: Niruri—Phyllanthus niruri L. (as “Phyllanthus lathyroides”); Swartziani—P. amarus Schumach. & Thonn. (as “Phyllanthus niruri”), P. lindbergii Müll. Arg., and P. stipulatus (Rafl.) G. L. Webster (as “Phyllanthus diffusus”); and Clasenian—P. acutifolius Poir. ex Spreng. Corrêa used the common names “Herva Pombinha” and “Quebra-Pedra.” The prevalent taxonomic confusion of names of species in sect. Phyllanthus in Corrêa’s synonymy is shared by most works on medicinal plants earlier in the 20th century. In contrast to Corrêa, whose illustration of Phyllanthus niruri is correct while his description (based on P. amarus) is misapplied, Matos (1989) correctly illustrates and applies the name Phyllanthus amarus. Matos considers that the vernacular name “Quebra-Pedra” is mainly applied to Phyllanthus urinaria L. (section Urinaria) in the Amazon, to P. amarus in the Nordeste, and to P. niruri (s. str.) in central and southern Brazil. The widespread confusion in applying Latin names to species in section Phyllanthus has become distracting due to the recent discoveries of anti-viral properties in several species, with possible significance for treating Hepatitis B and cancer (Blumberg et al., 1989). A taxonomically oriented survey of potential medicinal applications has shown that within Phyllanthus species of sect. Phyllanthus are of particular interest as potential sources of therapeutic compounds (Unander et al., 1991). It is hoped that this synopsis of the Brazilian species may prove to be useful for investigators of possible medical uses.

In the course of preparing this synopsis, I have become uncomfortably aware of its very provisional nature. At least two species complexes—Phyllanthus niruri/rosetellus in subsect. Niruri and P. lindbergii/microphyllus in subsection Swartziani—present so much variability and intergradation that the present treatment does not adequately present the reality; intensive field studies of these problematic populations are needed.

In Brazil there are species of 3 other sections of subgenus Phyllanthus that may be confused with those in section Phyllanthus. In order to avoid uncertainty as to whether or not an unidentified specimen is a species of section Phyllanthus, a key to the sections in Brazil is presented here.

**KEY TO THE SECTIONS OF SUBGENUS PHyllanthus IN BRAZIL**

1. Branchlets deciduous, with well-developed leaves; axes not dilated into phylloclades.
   
2. Stamens 5, filaments free; proximal cymes of branchlet bisexual; pollen grains 4-colporate; seeds puncticulate. **[P. tenellus Roxb.]** ....... 
   
   **Pentandra**

2. Stamens 2 or 3 (rarely 4), filaments free or more often partially to completely united; cymes of branchlet unisexual (except P. amarus); pollen grains 3- or 4-colporate; seeds striate, ribbed, or puncticulate.

   3. Pistillate flowers proximal on branchlet, staminate distal; seeds transversely ribbed; pollen grains 4-colporate; ovary verrucose. **[P. urinaria L]** ....... 
   
   **Urinaria**

   3. Pistillate flowers distal on branchlet, staminate proximal; seeds longitudinally ribbed, striate, or puncticulate; pollen grains 3- or 4-colporate; ovary usually smooth. .......
   
   **Phyllanthus**

1. Branchlets persistent, leaves usually reduced to scales; axes dilated into phylloclades. 

   **Choreotropsis**

**CONSPectus of the brazilian Taxa of Phyllanthus Section Phyllanthus**

Phyllanthus section Phyllanthus. **TYPE:** Phyllanthus niruri L.

**Subshrubs or herbs; monoecious or dioecious; Leaves alternate (opposite in P. almadensis), on penultimate axes usually (at least distally) reduced to scales; Flowers mostly in axillary glomerules; Sepals (4) 5 or 6; Stamens 2 or 3 (4), filaments free to completely connate; Anthers dehiscent vertically to horizontally, connective sometimes enlarged; Pollen grains mostly**
subprolate to prolate, 3- or 4-colporate, sexine reticulate to finely tectate-perforate; PISTILLATE DISK annular to cupular, sometimes lobed; OVARY 3-locular, glabrous (rarely papillose or pubescent); STYLES bifid (sometimes only emarginate); FRUITS capsular; seeds striate, finely ribbed, or puncticulate.

One of the largest sections of the genus, section Phyllanthus is pantropical, and includes nearly 100 species in 7 subsections (Webster, ined.). Five subsections occur in the neotropics, of which 4 are represented in Brazil (subsection Pentaphylii G. L. Webster is confined to the Caribbean).

KEY TO THE BRAZILIAN
SUBSECTIONS OF PHYLANTHUS
SECTION PHYLANTHUS

1. Branchlets with only 2 subopposite leaves, terminating in a racemose inflorescence; anther connective enlarged; pollen grains tectate-perforate.
   Subsect. 2. Almadenses
   1. Branchlets with > 10 alternate leaves, flowers in axillary cymes; anther connective enlarged or not; pollen grains reticulate to tectate-perforate.
   2. Seeds puncticulate; leaf blades mostly inaequilateral at base; cymes unisexual; pollen grains prolate, 4-colporate, exine reticulate; style-branches capitate.
   Subsect. 1. Niruri
   2. Seeds striate, ribbed, or puncticulate; leaf blades not (or scarcely) inaequilateral at base; cymes unisexual or bisexual; pollen grains subspheroidal to prolate, 3- or 4-colporate, exine reticulate to tectate-perforate; style-branches usually not capitate.
   3. Filaments connate; anther connective not appreciably enlarged, not deeply emarginate; pollen grains subspheroidal to prolate, 3-(4-) colporate; sexine finely reticulate to tectate-perforate; seeds longitudinally striate or ribbed (rarely puncticulate); branching strictly phyllanthoid, the distal leaves on penultimate axes reduced to cataphylls; branchlet axes usually not zig-zag.
   Subsect. 3. Swartziantha
   3. Filaments usually free; anther connective distinctly enlarged, deeply emarginate, the thecae discrete and sometimes stipitate; pollen grains mostly subspheroidal, 4-colporate, coarsely reticulate; seeds mostly puncticulate (sometimes striate); branching not phyllanthoid, leaves on penultimate axes not reduced to cataphylls in some species; branchlet axes often zig-zag.

HERBS OR SHRUBS; cataphyllar stipules linear-lanceolate; LEAF BLADES obliquely inaequilateral at base; SEPALS 5; stamens 3, filaments free or connate proximally; anthers dehiscing obliquely or horizontally; POLLEN GRAINS prolate, 4-colporate; pistillate disk patelliform; OVARY smooth and glabrous; STYLE free, bifid, tips subcapitate; SEEDS puncticulate.

This subsection of 5 species is restricted to America, although it is possible that the west African species Phyllanthus benguelensis may prove to belong here.

KEY TO THE BRAZILIAN SPECIES OF SUBSECTION NIRURI

1. Fruiting pedicels > 10 mm long; staminate sepals 1.9-2.4 mm long; stamens free. 1. P. augustinii
   1. Fruiting pedicels < 10 mm long; staminate sepals not over 1.8 mm long; stamens free or connate.
   2. Staminate sepals (1-) 1.2-1.8 mm long; seeds > 1 mm long.
   3. Staminate flowers with pedicels mostly 1-3 mm long, calyx yellowish or greenish; leaf blades mostly 7-17 mm long.
   Subsect. 2. P. niruri
   3. Staminate flowers with pedicels mostly 4-6 mm long, calyx ± reddish; leaf blades mostly 3-5 (-8) mm long.
   3. P. rosellus
   2. Staminate sepals 0.5-1 mm long; seeds < 1 mm long.
   4. P. perpusillus

This species remains poorly known; Müller (1873) stated that he had not seen
Bailon’s specimen. A collection from Rio de Janeiro at Kew (Glaziou 17757) has unusually large flowers and may represent **Phyllanthus augustini**.

**REPRESENTATIVE SPECIMENS:** **Acre:** Reserva Extrativista Chico Mendes, Pereira & Ming 102 (NY). **Amazonas:** Ilha do Yarary, Kuhlmann 388 (RB). **Bahia:** Mun. Santo Amaro: 10 km W of Santo Amaro, Webster, Dehgan, & Queiroz 25820 (DAV).

This highly variable and widespread neotropical species appears to represent a polyploid complex, with reported chromosome numbers of 2n = 14, 26, 36 (Mangenot *et al*., 1977). The circumscription of the species as adopted here must be regarded as tentative, and no attempt is made to formally recognize subspecific taxa. The specimens cited from Bahia and Rio de Janeiro represent *Phyllanthus lathyroides* var. *microcarpus* Müll. Arg., a delicate form with smaller parts that may prove to be distinguishable at a subspecific level.

**DISTRIBUTION AND HABITAT:** Cerrado and cerradão, often on sandy soils, 800–2000 m, extending into adjacent Argentina and Paraguay.

**REPRESENTATIVE SPECIMENS:** **Minas Gerais:** Baiendi, Brade & Apparicio 20456 (RB); Diamantina, Brade 13854 (RB); Serra do Caruca, Pohl (M), Pereira 2395, Pabst 2543 (RB); Serra da Moeda, Duarte 9697 (RB); 35–40 km E of Belo Horizonte, Irwin, Harley, & Onishi 30219, 30453 (DAV, NY). **Paraná:** 7 km E of Contendas, Krapovickas & Cristóval 39631 (CTES); 10 km W of Guarapuava, Reitz & Klein 17639 (US); Jaugariaiva, Smith, Klein, & Hattsbach 14748

It is with considerable diffidence that Phyllanthus rosellus is listed here as a distinct species. Müller (1863, 1866) originally regarded it as a form of *P. lathyroides* [P. niruri], but later elevated it to specific rank because of its solitary, “slightly larger” flowers, smaller leaves, and a dubious distinction in seed sculpturing. In Minas Gerais, *P. rosellus* appears clearly distinguishable from *P. niruri*, but small-leaved forms of the latter from Bahia and Rio de Janeiro are problematic. Allem (1977) has pointed out several problems in the taxonomic characterization of *P. rosellus*, and suggested that it be treated as a synonym of *P. niruri*.

1.4. **Phyllanthus perpusillus** Baill., Adansonia 1: 5; 358. 1865; Müll. Arg., Fl. Brasil. 11(2): 55. 1873; Webster, Sellowia 11: 169. 1959; Smith, Downs, & Klein, Fl. Ill. Catar. EUFO 51. 1988. **TYPE:** BRAZIL. Minas Gerais: Ponte Alta, A. St. Hilaire Cat. D, 301d (HOLOTYPE: P!; ISOTYPE FRAGMENT: A!). Webster (1959) pointed out that Müller’s description (1873) was based mainly on a collection of Pohl that appears not to be conspecific with St. Hilaire’s type collection.

**DISTRIBUTION AND ECOLOGY:** Recorded only from Minas Gerais and Santa Catarina, in campos, 750–1000 m. The apparently disjunct distribution of *Phyllanthus perpusillus* may be an artifact of collecting, since this diminutive species may have escaped detection (perhaps through confusion with species of subsection Swartziani).

**REPRESENTATIVE SPECIMENS:** Santa Catarina: Irani, Reitz & Klein 4707 (US); Mafra, Reitz & Klein 11502 (HBR, US); Rio Negrinho, Reitz 5200 (US).

Subsection 2. Almadenses G. L. Webster, subsect. nov. **TYPE:** Phyllanthus almadensis Müll. Arg.

Ab alis subsectionibus sectionis *Phyllantho* differt ramulis bifoliatis, foliis suboppositis, racemis terminalibus; anthers malliforos.

**HERBS,** monoeccious, glabrous, with single main stem; BRANCHLETS with a terminal pair of subopposite leaves, terminating in a raceme; bracts stipulate; proximal cymules stamine, distal bisexual; FLOW-ERS pedicellate; sepals 5; staminate disk segments 5; stamens 3, filaments free, anthers dehiscing laterally, with enlarged flattened connective, POLLEN GRAINS prolate, 3-colporate, exine tectate-perforate; PISTILLATE DISK cupular, entire; OVARY smooth; STYLES bifid, free; SEEDS unknown.

This subsection takes its name from the type (and only known) species, which was collected by Von Martius near Almada, in Bahia, Brazil. Because of the distinctiveness of the type species, a full description is provided. When Müller described *Phyllanthus almadensis* in the “Flora Brasiliensis” (1873), he noted its characteristic inflorescence, but grouped it with a number of unrelated species such as *P. attenuatus* Miq. and *P. sellowianus* Müll. Arg. Because he did not have a clear grasp of the significance of phyllanthoid branching, he failed to emphasize the extraordinary vegetative morphology of *P. almadensis*, in which the branchlets bear a single pair of opposite leaves and terminate in a racemose axis. This morphological pattern is unique in the entire genus *Phyllanthus*, and thus sets *P. almadensis* apart from all other species. A few New Caledonian species in subg. *Gomphidium* have branchlets with only 1 or 2 leaves (Schmid, 1991), but these do not subtend a terminal raceme as in *P. almadensis*. However, the flowers of this Brazilian species are similar in size and number of parts to species of section *Phyllanthus* as defined by Webster (1967, 1970). Furthermore, SEM observations on pollen morphology of *P. almadensis* (Webster and Carpenter, 2002) indicate a general resemblance to pollen grains of species in sect. *Phyllanthus* such as those described (using
light microscopy) by Punt (1962) and illustrated using SEM by Punt (1987) and by Punt and Rentrop (1974) and (for Mauritian species) by Bor (1979). It therefore appears reasonable to assign Phyllanthus almadiensis to a separate subsection in subgenus Phyllanthus section Phyllanthus.

The enlarged anther connective of Phyllanthus almadiensis suggests a possible affinity with subsection Clausfenian; however, the anther thecae are not distinctly separated, and the finely tectate-perforate pollen exine of P. almadiensis, as illustrated by Webster and Carpenter (2002), is quite different from the pollen exine of species of subsection Clausfenian, which is coarsely reticulate with lumina barca. Species of subsection Swartzian have pollen grains more similar in size (i.e., more prolate) and with finely tectate-punctate exine. However, in that subsection there is no approach to the vegetative, inflorescence, and anther morphology of Phyllanthus almadiensis. Thus, at present the relationships of subsection Almadensis have to be regarded as uncertain.

2.1 PHLANTHUS ALMADENSI MÜLL. ARG., Fl. Brasil. 11(2): 28. 1873. TYPE: BRAZIL. Bahia: sylvís ad lacum da Almada, I 1819. C. F. P. von Martius (HOLOTYPE: M; ISOTYPE: G). Taking into account the description of the Rio Almada by Paynter & Traylor (1991), the lake described by Martius appears on the “milionésimo” map (“Carta do Brasil ao Milionésimo”) at approximately 14°35' S, 39°06' W, c. 25 km NNW of Ilhéus. (Fig. 1)

MONECIOUS herb, annual or short-lived perennial, glabrous, 20–40 cm high, with single usually unbranched main stem. BRANCHED 1.5–2.5 cm long and 0.4–0.8 mm thick, terminating in a pair of opposite leaves that subdivide a terminal raceme. LEAF BLADES chartaceous, oblong-ovate, tapering to an obtuse or subacute tip, slightly paler abaxially, adaxially smooth (minutely alveolate); veins 5–10 per side, straightish, ± brochidodromous, scarcely raised, lacking a fine reticulum; margins plane; petiole 1–1.5 mm long; stipules dark, lanceolate, entire, 1.5–2.5 mm long. RACEMES terminal, slender, 4–8 cm long, with 7–15 nodes; proximal cymes staminate, mostly with 3–8 flowers, at distal nodes with solitary pistillate flower; bracts 1.2–1.5 mm long, narrowly lanceolate, appearing trid to the stipules. STAMINATE FLOWERS with pedicel 1.7–2.7 mm long; sepals 5, obovate, 1-veined, 1.7–2.2 mm long, 1–1.5 mm broad; disk segments 5, thickened, 0.3–0.5 mm across; stamens 3, filaments free, 0.7–1.7 mm long; anthers 0.3–0.5 mm long and broad, with flattened expanded connective, dehiscing laterally (± horizontally), POLLEN GRAINS prolate, 3-colporate, exine finely tectate-reticulate. PISTILLATE FLOWERS with pedicels 3–4 mm long; sepals 5, elliptic, 2.3–3.5 mm long; disk peltate, slightly cupular, 0.2 mm high, 1.0 mm broad; styles free, erect, ca. 1 mm long, shortly bifid, tips subcapitate. FRUITS and seeds not seen.

ADDITIONAL SPECIMENS EXAMINED: Bahia: Mun. Ilhéus, Piratáquises, Pimenta Vieilluso 903 (R); Mun. Itabuna, bairro Pedro Jerônimo, dos Santos 3614 (CEPEC, DAV).

Phyllanthus almadiensis appears to be restricted to a small area (ca. 30 km across) of the coastal rain forest (“mata atlantica”) in the vicinity of Ilhéus, Bahia (vegetation mapped by Bração & Araújo, 1981). Although Sr. dos Santos (personal communication) reported that it occurred within the city limits of Itabuna, my attempts to locate it there were unsuccessful.

Monecious or dioecious annual or perennial HERBS; branching strictly phyllanthoid (distal leaves on penultimate axes re-
duced to cataphylls); LEAVES acuilateral at base (or nearly so); STAMENS 2 or 3, filaments partially or wholly united; anthers mostly dehiscing horizontally, connective not enlarged, not deeply emarginate between the thecae; POLLEN GRAINS 3-collporate, exine finely reticulate or tectate-perforate; PISTILLATE DISK entire to lobed or dissected; ovary smooth; styles bifid, branches not capitate; SEEDS longitudinally
striate or ribbed (puncticulate in *Phyllanthus leptophyllus*).

This subsection of ca. 25 species is pantropical in distribution, with the main concentrations of species in America, Africa, and India. Most of the Brazilian species have been recently characterized in the treatment of species in Venezuelan Guayana by Webster (1999). In contrast to subsection *Clausenian*, there are no species of subsection *Swartzian* endemic to Brazil, except for *P. leptophyllus*, whose position in this subsection is doubtful. Only 5 of the 8 Brazilian species are commonly encountered; *Phyllanthus caribaeus*, *P. debilis*, and *P. leptophyllus* are only recorded from single specimens. The single introduced species, *Phyllanthus debilis*, might be confused with the exotic species *P. tenellus* Roxb. (section *Pentandra*), but the latter is easily distinguished by its longer fruiting pedicels and androecium of 5 free stamens. It is possible that an additional introduced species, *Phyllanthus fraterculus* G. L. Webster, has been found in Rio Grande do Sul (C. A. Machado, in litt.). It is vegetatively similar to *P. amarus*, but differs in its unisexual cymules and sharply angled scabridulous branchlet axes.

**KEY TO THE BRAZILIAN SPECIES OF SUBSECTION SWARTZIANI**

1. Cymules unisexual; the staminate flowers at proximal nodes of the branchlet; sepals obverse to rounded at tip.
2. Stamens 3 (rarely 2); monoeocious or dioecious; plants relatively robust, stems mostly at least 1.5 mm in diameter; staminate pedicels usually at least 0.5 mm long, sepals > 0.5 mm long; seeds at least 1.1 mm long.
3. Monoecious, filaments partially or completely united; anthers dehiscing horizontally or obliquely; seeds ribbed or finely striate; leaves mostly obverse or rounded at tip (except in *P. debilis*).
4. Deciduous branchlets terete; leaf blades obtuse to truncate at tip, often minutely scabridulous abaxially; seeds with 10–12 very fine longitudinal striae.
5. Pistillate disk 5-angled or lobed; filaments completely connate; stems often with basal aerialhypmy; pistillate sepals and leaf margins sometimes reddish-tinged. .... 1. *P. stipulatus*
6. Pistillate disk symmetrical; 3-lobed; filaments connate only in lower half; stems never with aerialhypmy; pistillate sepals and leaf margins not reddish. .... 2. *P. caribaeus*
7. Deciduous branchlets sharply angled; leaf blades ± pointed at tip, not minutely scabridulous abaxially; seeds with 6 or 7 longitudinal ribs. .... 3. *P. debilis*
8. Dioecious or subdioecious; filaments usually completely united; anthers dehiscing vertically or obliquely; seeds finely striate or puncticulate; leaves obverse at pointed at tip.
9. Stamens dehiscing vertically; staminate sepals 1.5–2.3 mm long; staminal column > 0.5 mm high; seeds 1.8–2 mm long. .... 4. *P. lindebergii*
10. Stamens mostly dehiscing obliquely; staminate sepals not over 1 mm long; staminal column mostly < 0.5 mm high; seeds < 1.5 mm long.
11. Seeds striate, 1.1–1.3 mm long; style branches not capitate. .... 5. *P. microphyllus*
12. Seeds puncticulate, 1.5–1.4 mm long; style branches capitate. .... 6. *P. leptophyllus*
13. Stamens 2 (rarely 3); monoecious; plants delicate, the stems mostly < 1 mm in diameter, staminate pedicels 0.2–0.5 mm long, sepals 0.4–0.5 (–0.7) mm long; seeds 0.9–1 mm long. .... 7. *P. minutulius*
14. Cymules all bisexual, each of 1 pistillate and 1 staminate flower; sepals acute. .... 8. *P. amarus*

*Phyllanthus hoffmannseggii* Müll. Arg., *Lin-
naca 32: 45. 1863. Type: BRAZIL, Pará, Hoffmannsegg s.n. (HOLOTYPE: B 179831).

**Distribution and Habitat:** Mexico and the West Indies south to Argentina and Brazil, moist forest and swamps, often growing in inundated areas, 0–1100 m.

**Representative Specimens:**

- **Acre:** Mun. Manoel Urbano, Colocação Nova Olinda, Daly et al. 9164 (DAV).
- **Amazonas:** Rio Purus, 2 km N of Labrea, Prance et al. 13719 (US).
- **Bahia:** Mun. Santa Cruz Cabrália: Estação Pau Brasil, Webster 25018 (CEPEC, DAV, NY, UEC, UFES).
- **Distrito Federal:** Reserva Ecológica do Guará, Pereira da Silva et al. 1694 (CEN, DAV).
- **Goiás:** Mun. Uruçu, 13 km NE of Vila Agua Branca, Walter et al. 1987 (CEN, DAV).
- **Maranhão:** Loreto, Eiten 3844 (SP).
- **Mato Grosso:** Mun. Cuiabá, Corrego Pinidaival, Hartschbach et al. 36068 (DAV, MBM).
- **Mato Grosso do Sul:** Mun. Corumbá, Fazenda Nhumirim, pantanal, Webster & Pott 25356 (DAV).
- **Minas Gerais:** Corinto, Mexia 5662 (TEX, US). Pará: Belém, São Joaquim, Barbosa da Silva 60 (US).
- **Roraima:** Serra Tepequem, Maguire 40006, Prance et al. 4256 (US).
- **São Paulo:** Mun. Paulínia, Calago 4256 (DAV).
- **Santa Catarina:** Pihões, Palhoça, Reitz & Klein 2781 (HBR).

Other than the ubiquitous *Phyllanthus amarus*, this is the most widespread Brazilian species of section *Phyllanthus*. Although not as diversified as *P. niruri*, it does show considerable variation in leaf shape. Sporadically occurring forms have elongated, more pointed leaves.

**Distribution and Habitat:** Native to East Asia, introduced sporadically into the neotropics, often in rice fields, 0–100 m.

**Specimen Examined:** Rio de Janeiro: Morro da Babilônia, Hoehne 25049 (SP).

Only one single collection has been recorded from Brazil in this study, but *Phyllanthus debilis* is also recorded from the Lesser Antilles (Guadeloupe) and Hawaii (Webster, 1957).

**Distribution and Ecology:** Colombia and Venezuela to Brazil and Paraguay, in swamps and wet savannas, 50–1100 m. In the northern part of its range, *Phyllanthus lindbergii* is sympatric in swampy areas with three other species of the subsection: *P. microphyllus*, *P. minutulus*, and *P. stipu-
latus. A number of plants with ambiguous characters occur here, suggesting the possibility of a hybrid complex.

**Representative Specimens: Amazonas:** Mun. Humaitá, Centeiochöniton & Janssen 389 (US). **Goiás:** Luziana, Heringer 17675 (US). **Mato Grosso:** Rio Brilhante, Hartsbach 30997 (DAV, US). **Minas Gerais:** Caldas, Regnell 1 404, 404a (US). **Paraná:** Foz de Iguacú, Schinini 8146 (CTES); Rio 10 km W of Guarapuava, Reitz & Klein 17614 (US); Jamaracarutu, Black et al. 57-19539 (DAV). **Santa Catarina:** Mun. Abelardo Luz, Smith & Klein 13847 (US); Mun. Campo Erê, Smith & Klein 13727 (HBR); Mun. Chapéu, Smith & Klein 9405, 11577 (HBR). **São Paulo:** Mun. Moji Guacu, 3 km NNW of Pâdua Sales, J. & N. Mattos 8226 (SP); Rio do Peixe, Edwall (SP 13722).

The “typical” form of *Phyllanthus lindbergii*, with large stamine flowers, vertically dehiscent anthers, and large seeds, is very distinct from the other species of subsection *Swartzianii*. However, particularly in the northern part of its range (Amazonian Brazil, Venezuela), the flowers and seeds are smaller. It is not clear whether this is due to hybridization with *P. microphyllus* and/or *P. stipulatus*.

**Distribution and Ecology:** Pantanal and other swampy or inundated areas, Venezuela south to Brazil, 100–250 m.

This species has long been misunderstood and confused with other species, such as *Phyllanthus lindbergii* and *P. stipulatus*. Müller (1873) cited no specimens from Brazil except for Riedel 2810, on which he based his variety *radicans* (which may be a form of *P. leptophyllus*), and he did not describe the stamine flowers.

3.6. **Phyllanthus leptophyllus** Müll. Arg., DC. Prodr. 15 (2): 411. 1866; Fl. Brasil. 11 (2): 57. 1873. **Type:** BRAZIL. **Minas Gerais:** Serra da Lapa, I 1825, L. Riedel 1008 (HOLOTYPE: B, destroyed; photograph, Pl!).

**Distribution:** known with certainty only from the type, a pistillate specimen from Minas Gerais. Müller (1873) distinguished it from *Phyllanthus microphyllus* by unconvincing vegetative characters and by the capitule style branch tips. However, since the seeds of *P. leptophyllus*, according to Müller’s description, are puncticulate, it is possible that it belongs to subsection *Clauseniana*.

3.7. **Phyllanthus minutulus** Müll. Arg., Fl. Brasil. 11 (2): 54. 1873; Cordeiro, Bol. Bot. Univ. São Paulo 13: 180, figs. 42–47. 1992; Webster, Fl. Venez. Guayana 5: 198, fig. 185. 1999. **Type:** BRAZIL. Goiás: Porto Imperial, 1828/29, W. J. Burchell 8486, 8533; Minas Gerais, G. H. von Langsdorff (SYN-TYPES, G?, not seen). Despite the fact that I have been unable to locate the types, Müller’s description seems so unambiguous
that there can be little doubt about the typification of the name.

**DISTRIBUTION AND HABITAT:** Colombia, southern Venezuela, and Brazil, in wet swamps and savannas (pantanais), 50–1100 m.

Phyllanthus minutulus appears to be one of the commonest and most widespread Brazilian species of section Phyllanthus, but it has often been overlooked or misdetermined because of its small size and superficial resemblance to small plants of _P. stipulatus_ or _P. microphyllus_. Jablonski (1967) misidentified the Spruce collection from Santarem as _P. microphyllus_.

**DISTRIBUTION AND HABITAT:** Apparently native to the Americas, but now pantropical, it is the weediest and most widespread species in the genus; in Brazil common in ruderal habitats, 0–1000 m. In publications before 1950, this species was usually called _Phyllanthus minuarii_ L., a misidentification made by Müller (1873).

Subsection 4. **Clausениани** G. L. Webster, subsect. nov. **TYPE**: *Phyllanthis clauseni* Baill.

Differt ab aliis subsectionibus sectionis *Phyllanthus* filamentiis liberiis, connectivo antherae dilatato, axes ramulorum saepe fractiopensis.

Monoecious or dioecious perennial HERBS or SUBSHRUBS; BRANCHES and leaves smooth or papillose-scabridulous; leaves on main axis reduced to cataphylls (in the majority of species); BRANCHLETS usually pinnatiform (sometimes branched in *P. subemarginatus*); FLOWERS pedicellate, in axillary clusters; sepals 6; STAMINATE FLOWERS with 3 stamens, filaments connate in *P. allemii* and *P. fastigiatus*; anthers deeply emarginate or the thecae distinct and stipitate; POLLEN GRAINS 4-corporate, subspheroidal, exine reticulate; STIGMATA flowers with patelliform disk; ovary smooth or papillose; styles free, bifid, branches not capitulate; SEEDS punculicate or striate.

As here defined, subsection *Clausениanium* clearly belongs in section *Phyllanthus* as indicated by its suffruticose habit, androecium of 3 stamens, and non-prolate pollen grains with relatively coarse reticum. The flowers and pollen are suggestively similar to those of species in the “leafless” broom-like species of sect. *Choretrepsis*. Although it is included here because of its characteristic androecium and pollen, *Phyllanthus subemarginatus* and related species are aberrant vegetatively, displaying little or no reduction in leaf lamina on the primary axes and generally ill-defined branchlets. *Phyllanthus heteradenius* and *P. ataiaensis* are also aberrant in appearance, resembling species of sect. *Loxopodium* (in subgenus *Isocladus*).

This subsection of 17 species appears to be entirely confined to Brazil, where it occurs in a variety of habitats: restingas, coastal rain forest, seasonal forest, montane forests, and subalpine campos rupestres. The subsection is similar in many respects to the West Indian subsection *Pentaphylli*, but differs in its cataphyllar stipules (which are not cordate and are blackened only in *Phyllanthus fastigiatus*); furthermore, species of subsection *Clausениanium* differ from the West Indian taxa in having punctulate seeds, usually free filaments, and (in some species) non-phyllanthoid branching.

### Key to the Species of Subsection *Clausениanium*

1. Distal leaf blades on penultimate axes reduced to cataphylls; branchlets smooth or papillose.
2. Branchlet axes smooth; anthers deeply emarginate (except in *P. mocotensis*) or thecae separate and stipitate.
3. Leaf blades mostly 3–6 cm long; stipules 4–5 mm long; fruiting pedicels 15–20 mm long, seeds 1.5–1.8 mm long. ........................................ 1. *Phyllanthus gauchovii*
4. Leaf blades, stipules, and fruiting pedicels, and seeds shorter.
5. Styles free (except sometimes at base), <1 mm long; leaf blades symmetrical or asymmetrical at base; fruiting pedicels 2–25 mm long; fruiting sepals 0.8–2.5 mm long.
6. Leaf blades symmetrical at base, not falcate, obtuse to rounded at apex; fruiting pedicels 2–15 mm long.
7. Leaf blades mostly 1 cm long or more, oblong to ovate or orbicular; branchlets not winged; anthers deeply emarginate or thecae separate and stipitate.
8. Stamineate calyx purplish-tinged; anthers deeply emarginate but thecae not stipitate; fruiting sepals ca. 2 mm long. .................. 2. *P. blanchetianus*.
9. Stamineate calyx not purplish; anther thecae distinctly stipitate; fruiting sepals 0.8–1.5 mm long.
10. Monoecious; sepals mostly 6; fruiting pedicels 6–18 mm long, sepals 0.8–1 mm long; seeds 1.3–1.5 mm long. ..................... 3. *P. clauseni*
9. Dioecious; sepalos mostly 5; fruiting pedicels 2–5 mm long, sepalos 1–1.5 mm long; seeds 1–1.2 mm long. 

7. Leaf blades < 1 cm long, oblong; branchlet axes winged; anthers slightly emarginate. 

6. Leaf blades falcate, asymmetrical at base, rounded to truncate at apex; fruiting pedicels 13–27 mm long. 

5. Styles connate into a column ca. 1 mm high; leaf blades mostly asymmetrical at base; fruiting pedicels 3–5 mm long, fruiting sepals 2.5–3 mm long. 

4. Leaf blades acute at tip, abaxially with whitish or yellowish coat of minute papillae; fruiting pedicels 9–12 mm long, sepals ca. 2 mm long. 

2. Branchlet axes papillose or scabridulous; anthers lightly to deeply emarginate.

10. Branchlet axes ± terete, at least not sharply winged.

11. Leaf blades ovate, rigid, acute, papillose or hirtellous abaxially; ovary papillose; stamens usually 2.

11. Leaf blades oblong, thin, obtuse, falcate, smooth or distinctly papillose abaxially; ovary smooth; stamens 3.

9. P. arenicola

8. P. italiciensis

12. Branchlet axes sharply angled or winged.

12. Leaf blades mostly ovate, acuminate, 10–20 mm long; monoecious; fruiting pedicels 6–11 mm long. 

10. P. acutifolius

12. Leaf blades broadly elliptic to suborbicular, obtuse or rounded at tip, 3–5 mm long; dioecious or subdioecious; fruiting pedicels 1.5–2 mm long. 

11. P. caparaoensis

1. Distal leaf blades on penultimate axes not reduced to cataphylls; branchlets smooth.

13. Stems, leaves, and flowers copiously reddish-hirsutulous; stamens 2; ovary hirsutulous.

12. P. piranhi

13. Stems, leaves, and flowers glabrous; stamens 2 or 3; ovary glabrous.

14. Stamens 3, filaments free; anthers emarginate.

15. Monoecious; branchlets not ramified; fruiting pedicel 1.2–5 mm long. 

16. Stamineate disk-segments falcate-acuminate; bracts of stamineate cymes neither glandular nor lobed/dissected; stamineate pedicels 0.1–0.5 mm long; seeds 1.1–1.4 mm long, punctulate-striate.

13. P. heteredentus

16. Stamineate disk-segments obturate; bracts of stamineate cymes glandular-lobed or -dissected; stamineate pedicels 2–3 mm long; seeds 1.7–1.8 mm long, finely striate.

14. P. atalaiensis

15. Dioecious; branchlets often ramified; fruiting pedicel 2–5 mm long; stamineate disk segments rounded.

15. P. subemarginatus

14. Stamens 2 or 3, filaments united in a column; anthers not clearly emarginate.

17. Stamens 3; branchlets conspicuously papillose-scabridulous; leaves pointed, not rigid; fruiting pedicel not clavate; seeds punctulate, without coarse cross-striae.

16. P. fastigiatus

17. Stamens 2; branchlets smooth; leaves apically truncate to emarginate, rigid; fruiting pedicel clavate; seeds punctulate-striate with coarse cross-striae.

17. P. allenii

**DISTRIBUTION AND HABITAT:** Paraná to Rio de Janeiro and southern Minas Gerais, in evergreen montane forest ( mata atlântica or matinha nebular), 50–1100 m.

Phyllanthus glaziouii is notable for its large acuminate leaves and large seeds, hav-
ing the aspect of species of subgenus *Xylo-
phyllum*. However, the colporate pollen grains
and deeply emarginate anthers suggest that
its closest affinity is in sect. *Clausenianii*.

4.2. **Phyllanthus blanchetianus** Müll.
Arg., Linnaea 32: 38. 1863; Fl. Brasil. 11(2):
45. 1873.

**TYPE:** BRAZIL. “parte meridionale
provinciae Bahia,” J. S. Blanchet 3158A
(NEWTYPE: G; ISOTYPE: P!).

**DISTRIBUTION AND HABITAT:** Endemic
to Bahia; not recollected as far as can be
determined. A poorly known species, possi-
ibly not belonging to this subsection.

4.3. **Phyllanthus clausenii** Müll. Arg.,
Linnaea 32: 40. 1863; DC. Prodr. 15(2):
401. 1866; Fl. Brasil. 11(2): 61, pl. 9 fig, 1.
1873. **TYPE:** BRAZIL. Minas Gerais: P.
Clausen 1530 (LECTOTYPE [designated
here]: W!). Müller cited no collection
numbers in 1863 and 1866, but cited three
Clausen collections in 1873; the specimen
at Vienna was the only one that could be
located.

**Phyllanthus clausenii** var. oblongofolius
**TYPE:** BRAZIL, Minas Gerais, Rioch
Fundo, 1834, L. Riedel 1364 (KI; perhaps
the holotype).

**DISTRIBUTION AND HABITAT:** Common
in thickets and woodland (sertão, cer-
radão), Ceará to Pernambuco, Minas Ger-
ais, and south to Paraná, 500-1100 m.

**REPRESENTATIVE SPECIMENS:** Ceará:
Mun. Novo Oriente: Ibiapaba, Araújo 322
(PEUFR); Sertão da Caridade, Ducke 2110
(MG). **Espírito Santo:** Goitacases, Rio
doce, Kuhlmann 6606 (RB). **Minas Gerais:**
Mun. Santana do Rio, Racho, Cordeiro
et al. CFSC 8228 (UEC), 43546
(SPF); Serra da Espinço, Pico do També,
Anderson, Stieber, & Kirkbridge 35931 (DAV,
NY); Vicosa, Mexia 5359 (MO, US). Parana:
Mun. Senges, Rio Itararé, Hacksbach
26741 (DAV). **Pernambuco:** Arcovere,
Chiopeito 938 (SP); Serra das Varas, Lima
56-2560 (PEUFR). São Paulo: Itaparanga,
Pickel 360 (US).

Specimens of *Phyllanthus clausenii*
have often been confused with *P. subemar-
ginatus*, but *P. clausenii* is usually mono-
cious, with 6-merous rather than 5-merous
perianth, and larger seeds (1.3-1.4 mm
long). Furthermore, in *P. clausenii* the dis-
tal leaves on penultimate axes are reduced
to cataphylls, and the branchlets are nor-
mally unramified. However, fragmentary
specimens without fruiting pedicels can be
difficult to distinguish.

4.4. **Phyllanthus mocotensis** G. L. Webster,
sp. nov.

**TYPE:** BRAZIL. Rio do Janeiro: Mun.
Santa Maria Madalena, Alto Mocotó, X
1933, J. Santos Lima 194 (HOLOTYPE: RB
26003!). (Fig. 3A)

A *P. tiatiaiensis* differs ramulis laevibus
anicipitibus, folios non falcatis, pedicellis
disquisibus; et *P. fastigiato* differs staminibus
liberis, ramulis laevibus.

Glabrous monoecious Herb with single
main stem; BRANCHLETS terete, smooth,
decurrent-winged on one side, 5-9 cm long,
0.5-0.6 mm thick, with 35-45 leaves. LEAF
BLADES oblong-obovate, obtuse-acute
at the tip, cuneate at base, 4-6 mm long, 2-4
mm broad; petioles < 1 mm long; stipules
subulate-acuminate, truncate at base, c.
1.5-2 mm long. STAMINATE FLOWERS 1-3
in proximal glomerules; sepals 5, ± orbi-
cular, 1-1.2 mm long; stamens 3, filaments
free, 0.6-0.8 mm long; anthers slightly
emarginate, dehiscing horizontally, c. 0.3
mm broad. PISTILLATE FLOWERS solitary
at distal nodes of branchlet, pedicel 5-6 mm
long in fruit; fruiting sepals 5, obovate, 1.2-
1.8 mm long; ovary 3-locular, styles bifid,
c. 0.5 mm long, branch tips subcapitate.
FRUITS and seeds unknown.
Known only from the type collection made by Santos Lima. The habit of *Phyllanthus mocotensis* is very similar to that of *P. fastigiatus* and *P. itatiaiensis*, but it appears morphologically distinct from the former in its typical phyllanthoid branching and the from latter in its non-falcate leaves.

4.5. *Phyllanthus carvalhoi* G. L. Webster, sp. nov.

**TYPE**: BRAZIL. Bahia: Mun. Itamarajú, Fazenda Pau-Brasil, mata higrófila sul Baiana, 160 m, 3 XI 1983, André M. de Carvalho, R. Calllelas & L. A. Mattos Silva 2022 (HOLOTYPE: CEPEC; ISOTYPES: DAV!, NY!). (Fig. 2, 3B)

Ab alis speciebus subsect. *Clausseniani* differt folis grandis falcatis ad basin inaequaliteribus; a *Phyllanthus sincorensis* differt stylis lberis, pedicellis fructiferis longioribus.

SUFFRUTICOSO monoeccious perennial, with a single main stem; main axis densely scabridulous; BRANCHLTS 7–12 cm long, 0.8–1 mm broad, with c. 20–30 leaves, axis terete, broadly winged, obscurely scabridulous in lines. LEAVES sessile or subsessile; leaf blades obovate, falcate-asymmetrical 1.0–1.5 cm long, 0.5–1.0 cm broad, truncate to rounded at apex, strongly inaequilateral at base, adaxially minutely aleate, abaxially purplish; lateral veins 3 or 4 pairs, arching, obscure adaxially but slightly raised abaxially; stipules lanceolate, 0.8–1 mm long; truncate at base. STAMINATE FLOWERS on bracteate brachyblasts up to 3 mm long at proximal axis, pistillate flowers solitary at apical 2 or 3 nodes of branchlet. Stamineate pedicel capillary, 5–8 mm long; sepals 5, free, obotato to suborbicular, entire, 1-veined, 1.5–2 mm long; disk segments 5, ± obcuneate, crenulate; stamens 3, filaments free, 0.8–1.2 mm long; anthers with enlarged deltoid connective but not emarginate, 0.5–0.6 mm broad, dehiscing horizontally. PISTILLATE FLOWERS solitary and axillary at 2–6 distal nodes of branchlet; pedicel 13–27 mm long; sepals 5, obovate, entire, midrib branching, carinate abaxially, 2–2.5 mm long in fruit; disk annular, ca. 1.3 mm broad; ovary smooth; styles spreading, deeply bifid, ca. 0.7–0.8 mm long, branches recurving. CAPSULES not seen entire; valves ca. 2.5–3 mm long; columella ca. 1.5 mm long; seeds ca. 2 mm long, punc- ticate-sтрат.

This highly distinctive species, named for André de Carvalho (student of the Bahian flora at CEPEC), is immediately separable from all other species of subsection *Clausseniani* by its winged branchlets with truncate, falcate, sessile leaves. *Phyllanthus itatiaiensis*, from Rio de Janeiro, has much smaller pointed, falcate leaves, but does not appear to be closely related.

4.6. *Phyllanthus sincorensis* G. L. Webster, sp. nov.

**TYPE**: BRAZIL. Bahia: Campos gerais, região Serra Sincorá, entre Brejão e Ilane- ma, 18 II 1943, Ricardo Lemos Frôes 20172 (HOLOTYPE: US!). (Fig. 3C)

Ab alis speciebus subsect. *Clausseniani* differt stylis connatis columnna sylorum 0.8–1 mm alto; ab *P. carvalhoi* differt folis petiolatis non falcatis; ab *P. claussenii* differt folis ad basin inaequalis.

Monoecious SHRUB, glabrous; BRANCHLTS terete, smooth, 10–12 cm long, 0.3–0.4 mm thick, with c. 25 leaves. LEAF BLADES ovate to oblong, 10–18 mm long, 5–11 mm broad, obtuse-apiculate at tip, obtuse to rounded or truncate and ± inaequilateral at base, veins prominent abaxially but not raised; petiole 1–1.5 mm long; stipules 1–2 mm long, acuminate. FLOWERS axillary, stamineate in glomerules at proximal axis, pistillate solitary at distal axis. STAMINATE pedicels 3–7 mm long; sepals 5 or 6, oblong, c. 2 mm long and 1.2 mm broad; disk segments 5 or 6, angular, ca. 0.3 mm long, stamens 3, filaments free, 1–1.5 mm long; anthers c. 0.4 mm broad, with enlarged connective, thecae discrete, dehis- cing ± horizontally. PISTILLATE pedicel 3–4 mm long in fruit; sepals 5, obovate, 1-
veined, 2.3–3 mm long, 0.8–1.3 mm broad and reflexed in fruit; disk petalliform, ca. 0.8–1 mm broad; ovary 3-locular; ovary smooth; styles erect, 1–1.2 mm high, connate into a column 0.8–1 mm high, tips bifid. SEEDS puncticate, 1.4 mm long.

Known only from the type collection. In its basally oblique leaf blades, *Phyllanthus sincorensis* appears similar to species of subsection *Niruri*. However, the anthers with enlarged connective suggest placement in subsection *Claussenian*.* The prominent
Fig. 3. Flowering branchlets of type specimens; *Phyllanthus* subsection *Claussenian*. A. *Phyllanthus mocotensis* (Santos Lima 194). B. *P. carvalhoi* (Carvalho et al. 2022). C. *P. sincorenis* (Lemos Frées 20172). D. *P. caparaoensis* (Wawra 1039).
styrac column separates it from all the other Brazilian species of section Phyllanthus.

DISTRIBUTION AND HABITAT: eastern Bahia and Espírito Santo, restinga and seasonal woodland (mata de cipó), near sea level to 1000 m.

As noted below, Phyllanthus hypoleucus is very similar to P. acutifolius; however, it occurs at lower elevations in drier vegetation types.

DISTRIBUTION AND HABITAT: Minas Gerais to Espírito Santo and Rio de Janeiro, restingas (lowland) and montane scrub, sea level to 1500 m. Cordeiro (1992) has noted that the plants of matas ciliares in Minas Gerais differ from the coastal populations in their pilose leaves; it is possible that they can be distinguished as an inland subspecies.

REPRESENTATIVE SPECIMENS: Espírito Santo: Vargem Alta, Fruteira, Pereira 2288 (HB, US). Minas Gerais: Serra do Cipó, Palácio, 150 km N of Belo Horizonte, Irwin, Maxwell, & Wasshausen 20576 (NY); Mun. Santana do Riacho, Vale do Córrego Vêu da Noiva, Cordeiro et al. 40735 (SPF), Rossi et al. 7005 (UEC), 36404 (SPF). Rio de Janeiro: Pedra Itauna, Maas & Carata 3137 (UB); Recreio dos Bandeirantes, Hoehne 5705 (SP, UEC); Restinga de Itaipu, Schwacke 7107 (RB), Warming 1697 (C); Restinga de Maricá, Webster et al. 25446 (DAV, R); Restinga da Barra da Tijuca, Kuhlmann s.n. (RB 111186), Pereira & Lima 5752 (DAV, MBM, R).

DISTRIBUTION AND HABITAT: Coastal range (Serra do Mantiqueira), Rio de Janeiro, subalpine scrub associated with Chusquea pinifolia, 2400–2600 m.

ADDITIONAL SPECIMENS EXAMINED: Rio de Janeiro: Macú de Itatiaia, Brade 20362 (RB), Glaziou 8927 (US), Gottsberger 110-15471 (UB), 134–17471 (DAV).

This diminutive species appears to be a narrow endemic to the Itatiaia massif. The falcate leaves distinguish it from those of most of the other species of subsect. Clausenianii, except for the much larger leaves of P. carvalhoii.

Phyllanthus oxyphylus Müll. Arg., Linnaea 32: 40. 1863 (nom. illeg.; non P. oxy-
phylus Miq., 1861). TYPE: "Brasilia mer-
dionali," F. Sellow (HOLOTYPE: B; de-
stroyed).

Gerais: Lagoa Santa, 1863/66, J. E. B. Warming 1586 (HOLOTYPE: G; ISOTYPE:
C!).

DISTRIBUTION AND HABITAT: Serra de
Mantequeira, Rio de Janeiro and adjacent
Minas Gerais and São Paulo, montane vege-
tation, 1100–1200 m. In Itatiaia, the spe-
cies occurs at lower elevations than Phyllan-
thus itatiaiensis.

REPRESENTATIVE SPECIMENS, Minas
Gerais: Baependi, São Tomé, Brade & Apparici 20467 (RB). Rio de Janeiro: Parque
Nacional Itatiaia, Altamiro & Walter 37
(MG), Brade 10322 (R), Sampaio 4687 (R),
Ule 213 (R); Lago Azul, Pereira, Egler, &
Maciel Barroso 69 (RB); Maromba, Pereira
6997 (US). São Paulo: São José do Barreiro,
Hoehne & Gert 17645 (SP).

Phyllanthus acutifolius is distinctive
within subsect. Claussenianii in its relatively
large ovate leaves and roughened branch-
lets. It is extremely similar in many respects
to P. hypoleucus of Bahia, which is clearly
its allopatric sister species. Although Müller
compared Phyllanthus lagoensis with P.
claussenii and P. subemarginatus, it appears
to be synonymous with P. acutifolius; the
characters in Müller’s key are not diagnosti-
c.

4.11. Phyllanthus caparaeensis G. L. Web-
ster, sp. nov.

TYPE. BRAZIL. Minas Gerais/Espírito
Santo: Serra do Caparaó, 1879 (?), H. Wa-
hra 1039 (HOLOTYPE: US 1234018!) (Fig.
3D).

Ab allis speciebus subsect. Claussenianii differt
plantis dioecios, foliis parvulis rotundatis coriaceis; a
P. arenicola differt foliis glabris, ramulis anciptibus.

SUFFERUTICOSE, dioecious or subdioec-
ioius, glabrous, 20–30 cm high; stems reddish-brown, finely channelled; BRANCHLET
axes ± compressed, winged, scabridulous,
3–12 cm long, 0.3–0.5 mm thick, with 10–
25 leaves. LEAF BLADES broadly elliptic to
suborbicular, rigid, 3–5 mm long, 0.25–5
mm broad; rounded or obtuse-apiculate at
tip, rounded to truncate or subcordate at
base, veins obscure on both faces; petiole
0.3–0.8 mm long; stipules acuminate, 0.7–
1.5 mm long. FLOWERS axillary, the sta-
minate in glomerules, the pistillate solitary.
STAMINATE pedicel (1-) 1.5–2.7 mm long;
sepal 5, rounded, 0.7–1.1 mm long; disk
segments 5, elliptic, smooth, 0.2–0.3 mm in
diameter; stamens 3; filaments free, 0.4–0.6
mm long; anthers deeply emarginate, 0.3–
0.4 mm in diameter. PISTILLATE pedicel
1.5–2 mm long; sepals 5, 1–1.2 mm long,
margins scarious; disk peltate; 1–1.2
mm in diameter; ovary 6-sulcate; styles free,
ascending, 0.4–0.5 mm long, bifid, branches
not capitate. SEEDS punctulate, 1.25 mm
long.

DISTRIBUTION AND HABITAT: Endem-
ic to the Serra da Caparaó on the border of
Minas Gerais and Espírito Santo, in subal-
pine vegetation, to 2400 m.

ADDITIONAL SPECIMENS EXAMINED: Mi-
nas Gerais: Serra do Caparaó, Brade 16989 ex
p. [mixed with P. subemarginatus] (DAV), Wa-
hra s.n. (US); Campos do Caparaó, VII 1888,
Schwacke (R), other than P. itatiaiensis.

Phyllanthus caparaeensis is distinctive in
its pale channelled stems, small rigid round-
ed leaves, and its occurrence on the slopes
of Pico da Bandeira at the highest elevations
of any Phyllanthus in Brazil.

4.12. Phyllanthus piranii G. L. Webster, sp.
nov.

TYPE. BRAZIL. Espírito Santo: Mun.
Conceição de Castelo, km 116 da BR 262,
24 XI 1982, J. R. Pirani, O. Yano, & D. F. Santos 230 (HOLOTYPE: SP 183289!). (Fig. 4, 5C)

Ab alis speciebus subsectionis Clauseniana diff-

fert ramulis foliisque hirsutulis, stipulis aciculis lon-
gioribus, pedicellis fructiferis brevibus.

HERB, monoecious, 20–30 cm high; STEMS persistent (lateral branches not de-
Fig. 5. Details of type specimens, Phyllanthus subsection Claussenian. A, B. Phyllanthus atalaiensis (Anderson 6911). C. P. piranii (Pirani et al. 230). D. P. allemii (Allem et al. 3041).
ciduous), sparsely branching, terete, slightly zigzag, up to 0.5 m long, 0.8–1 mm in diameter; axes and leaves hirsutulous with reddish-brown multicellular trichomes 0.2–0.7 m long. LEAF BLADES broadly elliptic to orbicular, obtuse to rounded at apex, rounded at base, hirsutulous adaxially and abaxially, lateral veins 4–6 per side, arching, obscure adaxially, prominent adaxially; petiole 1–1.5 mm long; stipules subulate-acuminate, entire, hirsutulous, 2.5–3.5 mm long. FLOWERS axillary, solitary, the staminate and pistillate at separate axils. STAMINATE pedicel ca. 3 mm long; sepals 5, 1.2–1.5 mm long; disk segments 5, elliptic, ca. 0.25 mm in diameter; stamens 2; filaments free, ca. 0.5 mm long; anther thecae spheroidal, 0.2 mm across, dehiscing horizontally. PISTILLATE pedicel 1.5–1.7 mm long in fruit, hirtellous; sepals in fruit 1.8–2.2 mm long; disk annular, thin; ovary hirsutulous with flattened trichomes ca. 0.1 mm long; styles 0.6 mm long, bifid, tips subcapitate. SEEDS puncticulate in longitudinal rows, 1.2 mm long.

Known only from the type collection in southern Espírito Santo. Phyllanthus piranii is named in honor of the collector, J. R. Pirani (Herbário, Depto. de Botânica, Universidade de São Paulo), a student of Brazilian campos rupestres. The species is very isolated in subsect. Clauseniata by the dense pubescence and the completely non-phyllanthoid branching; its assignment to the subsection must be regarded as provisional.

DISTRIBUTION AND HABITAT: northeastern Brazil, in caatinga and cerrado, 250–500 m.

REPRESENTATIVE SPECIMENS: Bahia: Espigão Mestre, 5 km. S of Cocos, Anderson et al. 37089A (DAV); Mun. Glória, 10 km N of Macurará, G. & L. T. Eiten 4965 (DAV). Paraíba: regiões xerófitas, Coelho de Moraes 2123 (US); Areia, near Alagoa de Renigio, Coelho de Moraes 741 (MG, RB). Pernambuco: 15 km S of Afrânio, Heringer et al. 333 (PEUFER).

Phyllanthus heteradenius is an unusual species, both for its habit which is very mimetic of the completely unrelated P. caroliniensis (sect. Loxopodium), and the remarkable falcate stamineate disk segments. Its only close relative within subsection Clauseniata appears to be P. atalaiaensis, which has similar stamineate disk segments.

4.14. PHYLANTHUS ATALAIENSIS G. L.Webster, sp. nov.

TYPE: BRAZIL. Goiás: Mun. Monte Alegre de Goiás, Serra da Atalaia, 25 km by road SW of Monte Alegre, forest on granitic rock, 600–800 m, 12 III 1973, W. R. Anderson 6911 (HOLOTYPE: US 2869354!). (Fig. 5A, B)

A P. heteradenius differt bracteis glandulos-issectis, pedicellis longioribus; ab aliis speciebus subsect. Clauseniata differt segmentis disco falcatis.

ANNUAL HERB, monoeocious, glabrous, 3–4 dm high; leaves on penultimate axes not reduced to cataphylls; BRANCHLETS terete, smooth, 4–7 cm long, 0.25–0.3 mm thick, with 7–10 leaves. LEAF BLADES broadly obovate to suborbicular, 5–10 mm long, 5–8 mm broad, margins densely scabridulous, petiole 1–1.5 mm long; stipules 0.5–1 mm long, apically glandular-dissected. FLOWERS axillary, stamineate in proximal glomerules, pistillate solitary and distal; bracts glandular-dissected as stipules. STAMINATE pedicel 2.5–3 mm long; sepals 5, broadly elliptic or suborbicular, 1-veined, 0.8–1.2 mm long; disk segments 5, massive, obtruncate, ca. 0.3 mm in diameter; filaments free, 0.3–0.4 mm long; anthers deeply emarginate. PISTILLATE pedicel ca. 2.5
mm long; sepals 5, obovate, pinnately veined, 2.7–3 mm long. SEEDS 1.7 mm long, with 5 or 6 dark narrow longitudinal stripes, very finely cross-striate.

Known only from the type collection, from northeastern Goiás near the borders with Tocantins and Bahia. Although in appearance Phyllanthus atlaiensis resembles a form of *P. heteradenius*, it differs from that species in its unusual lancinate stipules and bracts, a feature unique in sect. Phyllanthus.

**DISTRIBUTION AND HABITAT:** widespread and common in eastern Brazilian rain forests (mata atlântica) from Minas Gerais and Espírito Santo south to Santa Catarina, 400–1000 m.

*Phyllanthus subemarginatus* is the most problematic species of subsect. Clauisenianii. It is the only widespread species in the subsection that has leaves generally not reduced to cataphylls on the penultimate axes; it is deviant also in the repeated branching of the branchlets. However, in some specimens (e.g., Martinelli & Simonis 9056 from Serra dos Órgãos) there is a progression of increasingly reduced leaf blades on the main axis, with the uppermost leaves reduced to cataphylls. This suggests that the rather labile branching pattern in *P. subemarginatus* may reflect a “degeneration” from species of subsection Clauisenianii with typical phyllanthoid branching. Specimens with mostly unramified branchlets are superficially similar to *P. clausenii*, and the two species are often confused in herbaria; however, *P. subemarginatus* can be distinguished by its dioecious flower production and shorter fruiting pedicels (2–5 mm long vs. 7–18 mm in *P. clausenii*).

The status of *Phyllanthus amoenus* Müll. Arg. appears questionable. Müller distinguished it from *P. subemarginatus* by
having true phyllanthoid branching and larger differently veined leaves. However, it appears to fall within the overall range of variation of *P. subemarginatus*. *Phyllanthus reflexus* Brade appears to represent an unusually diffusely branching form.

4.16. **Phyllanthus fastigiatus** Mart. ex Müll. Arg., Linnaea 32: 45. 1863; Fl. Brasil. 11(2): 57. 1873. **TYPE**: BRAZIL. Minas Gerais: Serra Itacolomi, Morro de Vila Rica, IV 1818, C. F. P. von Martius s.n. (LECTOTYPE [designated here]: M); holotype at B destroyed). The typification is somewhat problematic because Müller in 1863 ascribed the species to “Mart. mss. in herb. Berol.”, but cited only collections by Riedel and Sellow (presumably the reference to a Martius specimen was implicit, because an annotation label by Müller of the specimen at M indicates the original collection was made by Martius).

**Distribution and Habitat**: Scrub on rocky slopes, Minas Gerais, two disjunct localities in Serra da Moeda and Serra do Espição, near Ouro Preto, to 1750 m.

**Specimens Examined**: Minas Gerais: Mun. Itabirito, Monte Itabira, II 1835, Lund 1439 (G); Mun. Mariana, Serra do Itacolomi, Damazio (RB 18685), Damazio 1606 (RB 7870), Schwacke 14483 (RB), Ule 2686 (R).

*Phyllanthus fastigiatus*, which appears to be narrowly endemic to the region around Ouro Preto, is readily recognized among species of subsect. *Claussenian* by its virgate habit (somewhat resembling Greater Anrtleean species of subsect. *Pentaphylli*) with narrow pointed leaves and by its muticus (non-emarginate) anthers.

4.17. **Phyllanthus allemi** G. L. Webster, sp. nov.

**TYPE**: BRAZIL. Goiás: Mun. Taguatinga, 7 km NE of Taguatinga towards Barreiras, cerrado, 850 m, 19 XI 1984, A. C. Allem, G. L. Webster, & W. E. Werneck 3041 (HOLOTYPE: CEN!; ISOTYPE: DAV!). (Fig. 5D).

Ab alii speciebus Brasiliensibus sectionis *Phyllantho* differt folis coriaceis, pedicellis fructiferis clavatis, seminibus majoribus, testa longitudinaliter puncticulato-serrate transversaliter hispidulo-stricto.

**Perennial** herb, monoeocious, glabrous, sparsely ramifying, 0.5–1 m high; leaves on penultimate axes not reduced to cataphylls; branchlet axes terete, smooth, 3–5 cm long, with 10–20 leaves. Leaf blades suborbicular, rigid and coriaceous, 3–5 mm long and broad, rounded to emarginate at tip, obtuse to truncate at base; petiole c. 0.5 mm long; stipules acuminate, 0.5–0.8 mm long. Flowers axillary, cymules unisexual, pistillate flowers solitary in distal axils, staminate flowers 1 or 2 at proximal axils. Staminate pedicel 1–1.2 mm long; sepals 5, obovate, 1.0–1.1 mm long, 0.5–0.7 mm broad; disk segments 5, elliptic, 0.25–0.3 mm in diameter; stamens 2, filaments completely connate into a column ca. 0.6 mm high; anthers sessile on the column, dehiscing obliquely, 0.25–0.3 mm broad. Pistillate pedicel in fruit clavate, 3–5 mm long and 0.5–0.7 mm in diameter apically; sepals 5 or 6, elliptic, the outer 1.1–1.2 mm long, the inner 1.4–1.6 mm long; disk annular, pitted, ca. 1.3 mm in diameter; styles spreading, bifid, ca. 0.5 mm long. Capsule oblate, 4 mm in diameter; columella ca. 1.5 mm long; seeds trigonous, brownish, 1.8–2 mm long, longitudinally finely puncticulato-serrate, with coarse stigose cross-striae.

Known only from the type collection. Although its general habit suggests small-leaved specimens of *P. subemarginatus*, the clavate fruiting pedicels, stamen number, and large seeds with different ornamentation of *P. allemi* clearly set it apart. In its lack of reduction of the leaf blades on penultimate axes and its androecium of two corneate stamens, *P. allemi* seems closest to
P. fastigiatum. However, it is easily distinguished from that species by its smooth (non-scalbrid) axes, thicker and blunter leaves, and much larger seeds. It is a pleasure to dedicate this distinctive species to Dr. Antonio Costa Allem, of EMBRAPA/CENARGEN (Brasilia), a leading expert on Euphorbiaceae of Brazil, who was both guide and colleague on the extended botanizing trip from Brasilia to remote stretches of Minas Gerais, Bahia, and Goiás during which this species was discovered.

ACKNOWLEDGMENTS

This study has been made possible through the cooperation of many collaborators during my trips to Brazil, including Atonio Costa Allem (EMBRAPA/CENARGEN, Brasilia); André M. de Carvalho (CEPEC, Itabuna); Inês Cordeiro (Instituto de Botânica, São Paulo); Margarete Emmerich and associates (Museu Nacional, Rio de Janeiro); Gert Hantschbach (Museu Botânico Municipal, Curitiba); Afrânio Gomes Fernandes and F. J. Abreu Matos (Universidade Federal do Ceará, Fortaleza); Fernando and Eleona Martins, and Yoshiho Tashiro (Departamento de Botânica, Universidade Estadual de Campinas); Arnildo and Vali Pott (Herbário EMBRAPA, Corumbá); Luciano P. de Queiroz (Universidade Federal de Feira de Santana); Maria J. N. Rodal and colleagues (Universidade Federal Rural de Pernambuco); Ricardo Secco (Museu Paraense Emílio Goeldi, Belém), and Marcus Sobral (Universidade Federal do Rio Grande do Sul, Porto Alegre). Logistic support was provided by grants from the National Science Foundation, the National Geographic Society, the Smithsonian Institution, and from the Academic Senate, University of California, Davis. Ellen Dean, Director of the Herbarium (DAV) at the University of California, Davis, and Jean Shepherd, the Curator, displayed infinite patience with the process of handling a large number of loans of specimens. Thanks are also due to the curators of the herbar-
